The battery OTOH, powers (because of a board bug) part of the VIA. If such power fails, the VIA beings to bitch out, the date being not kept is just one of the symptoms - the others, you experienced them in first person.

Ah! At least, a reasonable-sounding explanation of why the battery causes so many problems.

Chris

If one adapts rechargeable batteries (3xAA=3.6V, they are pretty cheap, 2000+mAh each) with an adapter that plugs into 5 or 12V line of the PSU with proper diode (or whatever it should be, apologies for possible ignorance in electronics)? Or 3.6V will kill something? Anyone? Shouldn't be to complicated for DIY imho.

Jack
