GDB do many-many thinks. Tons of docs about GDB are avail in the net (just in google: gdb documentation). [There is](#) one of them. And [there is](#) wikipedia description. To easy understand - GDB is the best and widely usable debugger in unix world (so, it's mainly for programmers/coders/hackers/etc).

We already have port of it on OS4, and, it can starts, it can load the ELF files, and process some disassembly outputs, works a bit, but, have many bugs, which cause frezes of OS, hatls, gurus and reboots. And the main goal of topicstart, make a bounty for "normal port" of GDB, which will works fine, will up2date, and we all will enjoy by it usage.

That must be done by Hyperion of course (if they use it, and have it in SDK), but by some reassons is not, and version which we have from they buggy like hell.
