However, the OS4 Screens preferences program enables system created screens that are opened automatically whenever a program attempts to open on a screen with that name.

As I said, if there is such a mechanism, then this mechanism is responsible for closing the screen, just like any other application.

And it must be possible for that mechanism and any other application to rely on the notification system (SA\_PubSig, SA\_PubTask) in order to know when the last visitor window disappears.

If Ringhio destroys the notification because it does not use the normal LockPubScreen/UnlockPubScreen and/or OpenWindow/CloseWindow functions, then it is just bad software and should be fixed.
