There is a Kickstart component called "diskboot.kmod", maybe that calls itself "diskboot.config" when running, or spawns a task that calls itself that.

If I weren't so busy (Read: lazy), I could look up the sources and find out. But look at it this way: when your program crashes in Exec, you don't blame Exec for the crash, you blame your program, don't you?

In this case, Quake is calling a newlib function that ends up in a crash. It's most likely that the crash is quake's fault. It is probably caused by some old coding trick that *used* to work back in the old days, but has been made illegal these days.
